Supplemental File of

MicrobiotaProcess: A comprehensive R package for managing and analyzing microbiome and other ecological data within the tidy framework

Shuangbin Xu, Li Zhan, Wenli Tang, Zehan Dai, Lang Zhou, Tingze Feng, Meijun Chen, Shanshan Liu, Xiaocong Fu, Tianzhi Wu, Erqiang Hu and Guangchuang Yu*

1 Installation

To install MicrobiotaProcess package, please enter the following command in R:

```
if (!requireNamespace("BiocManager", quietly = TRUE))
  install.packages("BiocManager")
BiocManager::install("MicrobiotaProcess")
```

To reproduce the analysis in this document, the several extra packages also needed to be installed.

```
cranpkgs <- c("aplot", "ggpp", "igraph",</pre>
               "broom", "forcats",
               "ggrepel", "ggVennDiagram",
               "patchwork", "shadowtext",
               "ggupset", "ggnewscale")
for (i in cranpkgs){
    if (!requireNamespace(i, quietly = TRUE)){
        install.packages(i)
    }
}
Biocpkgs <- c("SummarizedExperiment", "clusterProfiler",</pre>
               "edgeR", "enrichplot", "tidybulk",
               "ggtree", "ggtreeExtra", "MicrobiomeProfiler")
for (i in Biocpkgs){
    if (!requireNamespace(i, quietly = TRUE)){
        BiocManager::install(i)
    }
}
```

2 Analysis of 16s rDNA dataset about 43 pediatric CD stool samples from iHMP

Here, we use the 43 pediatric IBD stool samples as example, which were obtained from the Integrative Human Microbiome Project Consortium (iHMP) (Research Network Consortium 2014).

2.1 Importing the output of dada2

The datasets were downloaded from web¹. These datasets contain ibd_asv_table.txt (feature table (row features X column samples)), ibd_meta.csv (metadata file of samples), and ibd_taxa.txt (the taxonomic annotation of features). In the session, we use mp_import_dada2 of MicrobiotaProcess to import the dataset, and return an MPSE object.

^{*}correspondence: Guangchuang Yu <gcyu1@smu.edu.cn>

```
sampleda <- read.csv("./data/IBD_data/ibd_meta.csv", row.names=1, comment.char="")</pre>
taxda <- read.table("./data/IBD_data/ibd_taxa.txt", header=T,</pre>
                   row.names=1, check.names=F, comment.char="")
# the feature names should be the same with rownames of taxda.
taxda <- taxda[match(colnames(otuda), rownames(taxda)),]</pre>
mpse <- mp_import_dada2(seqtab = otuda, taxatab = taxda, sampleda = sampleda)</pre>
# view the reads depth of samples and the prevalence of the OTUs. In this example,
# mpse %>% mp extract assay(.abundant=Abundance) %>% rowSums() %>% sort %>% head(100)
# mpse %>% mp_extract_assay(.abundant=Abundance) %>% colSums() %>% sort %>% head()
# Or
# head(sort(rowSums(assay(mpse, "Abundance"))), 100)
# head(sort(colSums(assay(mpse, "Abundance"))))
# In this example, we can find some OTUs have very low frequency in the samples.
# and some taxonomy are unreasonable, for example, the probability of chloroplasts
# in the intestine should be low. We can also remove the features.
mpse2 <- mpse %>%
        dplyr::filter(!Phylum %in% c("p_un_k_Bacteria", "p_Chloroflexi") &
                       !Class %in% "c__Chloroplast" &
                       !Family %in% "f_mitochondria"
        ) %>%
        mp_filter_taxa(.abundance = Abundance, min.abun = 1, min.prop = 0.1)

2.2 Other import functions

building the output format of removeBimeraDenovo of dada2

otuda <- data.frame(t(otuda), check.names=F)</pre>

MicrobiotaProcess also presents some other import functions S1 to parse the output of the upstream pipelines. In addition, some common object of R can also be converted to MPSE object, such as phyloseq (McMurdie 2013), SummarizedExperiment (Morgan et al. 2021), TreeSummarizedExperiment (Huang et al. 2021), biom (McMurdie and Paulson 2021) (output of biomformat by read_biom) referring to chapter 3.1.

Table S1: List of import functions provided by MicrobiotaProcess

Package	Import Function	Description
	mp_import_qiime2	Import function to load the output of qiime2
${\bf MicrobiotaProcess}$	mp_import_qiime	Import function to read the now legacy-format QIIME OTU table (tsv format)
	$mp_import_metaphlan$	Import function to read the output of MetaPhlAn

2.3 alpha diversity analysis

2.3.1 rarefaction visualization

Rarefaction, based on sampling technique, was used to compensate for the effect of sample size on the number of units observed in a sample. MicrobiotaProcess provided $mp_cal_rarecurve$ and $mp_plot_rarecurve$ to calculate and plot the curves.

```
library(MicrobiotaProcess)
library(patchwork)
cols <- c("orange", "deepskyblue")</pre>
mpse2 %<>%
    mp_rrarefy(.abundance=Abundance) %>%
    mp_cal_rarecurve(.abundance=RareAbundance, chunks=500)
p_rare <- mpse2 %>%
          mp_plot_rarecurve(
            .rare = RareAbundanceRarecurve,
            .alpha = c(Observe, Chao1, ACE),
          ) +
          theme(
            legend.key.width = unit(0.3, "cm"),
            legend.key.height = unit(0.3, "cm"),
            legend.spacing.y = unit(0.01, "cm"),
            legend.text = element_text(size=4)
          )
prare1 <- mpse2 %>%
          mp_plot_rarecurve(
            .rare = RareAbundanceRarecurve,
            .alpha = c(Observe, Chao1, ACE),
            .group = Group
          ) +
          scale fill manual(values = cols)+
          scale_color_manual(values = cols)+
          theme bw()+
          theme(
            axis.text=element_text(size=8), panel.grid=element_blank(),
            strip.background = element rect(colour=NA, fill="grey"),
            strip.text.x = element_text(face="bold")
          )
prare2 <- mpse2 %>%
          mp_plot_rarecurve(
            .rare = RareAbundanceRarecurve,
            .alpha = c(Observe, Chao1, ACE),
            .group = Group,
            plot.group = TRUE
          ) +
          scale_color_manual(values = cols)+
          scale fill manual(values = cols) +
          theme bw()+
          theme(
            axis.text=element_text(size=8), panel.grid=element_blank(),
            strip.background = element_rect(colour=NA,fill="grey"),
            strip.text.x = element_text(face="bold")
(p_rare / prare1 / prare2) + patchwork::plot_annotation(tag_levels="A")
```

Fig. S1: This example show *MicrobiotaProcess* provided $mp_cal_rarecurve$ and $mp_plot_rarecurve$ to calculate and visualize the rarefaction curve. The horizontal coordinate represents the sequencing depth of samples, the vertical coordinate shows the Alpha diversity index (such as Observe OTU, Chao1 and ACE). The $mp_plot_rarecurve$ provides three types of visualization. (A) the rarefaction curve for each sample. (B) the rarefaction curve for each sample with colored group (specified *.group* argument in $mp_plot_rarecurve$). (C) the rarefaction curve for each group with standard error of the mean (specified *.group* argument and plot.group=TRUE in $mp_plot_rarecurve$)

2.3.2 Calculation and different analysis of alpha diversity

Alpha diversity can evaluate the richness and evenness of microbial communities. MicrobiotaProcess provides mp_cal_alpha to calculate alpha index. Six common diversity measures (Observe, Chao1, ACE, Shannon, Simpson, Pielou) are supported. The result can be visualized by mp_plot_alpha . This following example shows how to use mp_cal_alpha and mp_plot_alpha of MicrobiotaProcess to analysis the alpha diversity of the community. The RareAbundance is rarefied (default), which will be used to calculate the alpha diversity index, users can specify the force=TRUE of mp_cal_alpha to calculated the alpha diversity if the abundance is not be rarefied (referring to chapter 3.3.1).

Fig. S2: The raincloud plot of alpha diversity index The horizontal coordinate represents each group (by .group argument of mp_plot_alpha), the vertical coordinate represents the alpha diversity index.

2.4 Taxonomy composition analysis

2.4.1 Statistics and visualization of specific levels

MicrobiotaProcess presents the $mp_cal_abundance$ and $mp_plot_abundance$ for the calculation and visualization of composition of microbial communities. After the $mp_cal_abundance$ done, you can get the abundance of specific levels of class by $mp_extract_abundance$ (referring to chapter 2.5.4).

```
library(ggplot2)
library(MicrobiotaProcess)
# The relative abundance of all taxonomy for samples will be calculated
mpse2 %<>% mp_cal_abundance(.abundance = RareAbundance)
# The relative abundance of all taxonomy for group will be calculated
mpse2 %<>% mp_cal_abundance(.abundance = RareAbundance, .group = Group)
# The 30 most abundant taxonomy will be visualized.
pclass <- mpse2 %>%
          mp_plot_abundance(
             .abundance = RareAbundance,
             .group = Group,
             taxa.class = Class,
             topn = 30
          ) +
          xlab(NULL) +
          ylab("relative abundance (%)") +
          theme(
             legend.key.width = unit(0.3, "cm"),
             legend.key.height = unit(0.3, "cm")
          ) +
          xlab(NULL) +
          ylab("relative abundance (%)") +
          theme(
             legend.key.width = unit(0.3, "cm"),
             legend.key.height = unit(0.3, "cm"),
             legend.text = element_text(size=6)
```

pclass)

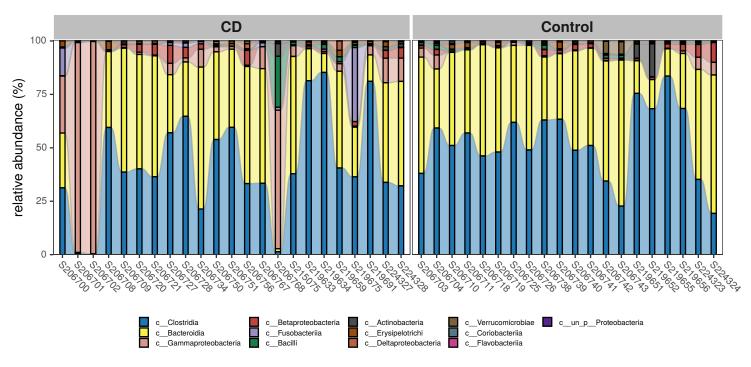

Fig. S3: The relative abundance of each sample in class level

The relative abundance of groups also can be visualized by providing .group argument and setting plot.group=TRUE in the $mp_plot_abundance$. If you want to view the raw abundance (count or others) of taxa, you can set the relative parameter of $mp_plot_abundance$ to FALSE.

```
# Show the abundance in different groups.
fclass <- mpse2 %>%
          mp_plot_abundance(
             .abundance = RareAbundance,
             .group = Group,
             taxa.class = Class,
             topn = 30,
             plot.group = TRUE
          ) +
          xlab(NULL) +
          ylab("relative abundance (%)") +
          theme(legend.position = "none")
pclass2 <- mpse2 %>%
          mp_plot_abundance(
             .abundance = RareAbundance,
             .group = Group,
             relative = FALSE,
             taxa.class = Class,
             topn = 30
          ) +
          xlab(NULL) +
          ylab("count reads") +
          theme(legend.key.width = unit(0.3, "cm"),
                 legend.key.height = unit(0.3, "cm"),
                 legend.text = element_text(size=6)
          )
aplot::plot_list(pclass2, fclass, widths=c(10, 1), tag_levels = "A")
```

Fig. S4: This example show how to displayed the abundance (count or other) of sample and the relative abundance of groups. The Abundance (count by rarefied) of each sample (A) and the relative abundance of group (B), these results show the *Gammaproteobacteria* of *CD* group might be more abundant than the *control* group.

The abundance of features also can be visualized by mp_plot_abundance with heatmap plot by setting geom="heatmap".

```
hclass1 <- mpse2 %>%
          mp plot abundance(
             .abundance = RareAbundance,
             .group = Group,
             taxa.class = Class,
             topn = 30,
             geom = "heatmap"
          set_scale_theme(
            x = list(scale_fill_viridis_c(option = "H"),
                     theme(
                       axis.text.x = element_text(size = 6),
                       axis.text.y = element_text(size = 7),
                       legend.title = element_text(size = 7),
                       legend.text = element_text(size = 5),
                       legend.key.width = unit(0.3, "cm"),
                       legend.key.height = unit(0.3, "cm")
                     )
                ),
            aes_var = RelRareAbundance
          ) %>%
          set_scale_theme(
            x = list(scale_fill_manual(values = cols),
                     theme (
                       legend.key.height = unit(0.3, "cm"),
                       legend.key.width = unit(0.3, "cm"),
                       legend.spacing.y = unit(0.02, "cm"),
                       legend.text = element_text(size = 7),
                       legend.title = element_text(size = 9)
                     )
                ),
```

```
aes_var = Group
           )
hclass2 <- mpse2 %>%
           mp_plot_abundance(
               .abundance = RareAbundance,
               .group = Group,

                                                                                                      c Bacteroidia
                                       un p Proteobacteria
                                                                                                      un p Proteobacteria
                                       Flavobacterija
                                                                                                      Flavobacterija
```

Fig. S5: The heatmap of abundance for each sample in *class* level. The color (continuous) of heatmap represents the abundance of taxon, the color of bar represents the group name of sample, the horizontal coordinate represents the sample, and the vertical coordinate represents the taxon.

2.4.2 Venn or Upset plot

The Venn or UpSet plot can help us to obtain the difference between groups in overview. MicrobiotaProcess provides $mp_cal_venn \ (mp_plot_venn)$ and $mp_cal_upset \ (mp_plot_upset)$ to perform the Venn and Upset analysis.

```
mpse2 %<>%
    mp_cal_venn(
      .abundance = RareAbundance,
      .group = Group
    )
venn_p <- mpse2 %>%
    mp_plot_venn(
      .group = Group,
      set_size = 2.5,
      label_size = 2,
      edge_size = 2.5
    ) +
    scale_colour_manual(values = cols) +
    scale_fill_viridis_c(guide = guide_colorbar(barwidth=.3, barheight=2)) +
      legend.title = element_text(size = 8),
      legend.text = element_text(size = 6)
mpse2 %<>%
    mp cal upset(
      .abundance = RareAbundance,
      .group = Group
upset_p <- mpse2 %>%
    mp_plot_upset(
      .group = Group
    ) +
    theme_bw() +
      plot.background = element_blank(),
      panel.border = element_blank(),
      panel.grid = element_blank(),
      axis.line.x.bottom = element_line(size = .5),
      axis.line.y.left = element_line(size = .5)
    ggupset::theme combmatrix(
      combmatrix.label.extra_spacing = 40
library(ggpp)
p.up.venn <- upset_p +</pre>
             ggpp::annotate(
               "plot_npc",
               npcx = "right",
               npcy = "top",
               label = venn_p,
               vp.width = 0.6,
               vp.height = 0.4
p.up.venn
```

2.5 beta analysis

2.5.1 PCA analysis

PCA (Principal component analysis) and PCoA (Principal Coordinate Analysis) are general statistical procedures to compare dissimilarity of samples. And PCoA can based on the phylogenetic or count-based distance metrics, such as Bray-Curtis, Jaccard, Unweighted-UniFrac and weighted-UniFrac. *MicrobiotaProcess* presents the mp_cal_dist , mp_cal_pca , mp_cal_pca , mp_cal_dist , mp_cal_pca , mp_cal_pca , mp_cal_dist , mp_anosim , mp_anosi

```
library(MicrobiotaProcess)
library(patchwork)
# hellinger transform
mpse2 %<>%
    mp_decostand(
        .abundance = Abundance,
        method = "hellinger"
    )
mpse2 %<>% mp_cal_pca(.abundance = hellinger)
# Visulizing the result
pcaplot1 <- mpse2 %>%
            mp plot ord(
              .ord = pca,
              .group = Group,
              .starshape = Group,
              .size = Observe
```

```
scale_fill_manual(values = cols) +
            scale_size_continuous(
              range = c(1, 3),
              guide = guide_legend(override.aes = list(starshape = 15))
            ) +
            theme(
              legend.key.width = unit(0.3, "cm"),
              legend.key.height = unit(0.3, "cm"),
              legend.text = element_text(size = 6),
              legend.title = element_text(size = 7)
# .dim = c(1, 3) to show the first and third principal components.
pcaplot2 <- mpse2 %>%
            mp_plot_ord(
              .ord = pca,
              .dim = c(1, 3),
              .group = Group,
              .starshape = Group,
              .size = Observe
            ) +
            scale_fill_manual(values = cols) +
            scale_size_continuous(
              range = c(1, 3),
              guide = guide_legend(override.aes = list(starshape = 15))
            ) +
            theme(
              legend.key.width = unit(0.3, "cm"),
              legend.key.height = unit(0.3, "cm"),
              legend.text = element_text(size = 6),
              legend.title = element_text(size = 7)
(pcaplot1 | pcaplot2) + plot_annotation(tag_levels = "A")
```

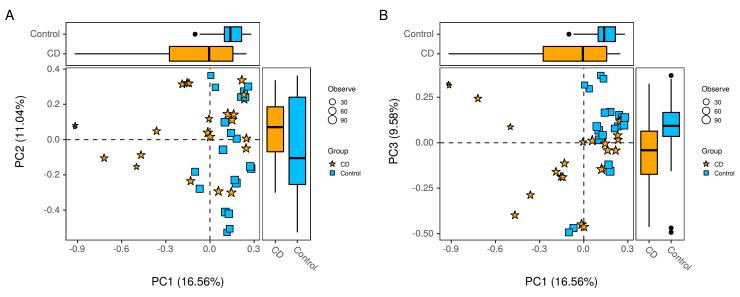

Fig. S7: The PCA plot of the community. Each point represents one sample, the size of point represents the observe OTU of the sample. The color of point represents the group name of the sample, based on the first and second component (A), based on the first and third component (B).

2.5.2 PCoA analysis

```
# distmethod
# "unifrac",
              "wunifrac", "manhattan", "euclidean", "canberra", "bray", "kulczynski" ... (veqdist, dist)
mpse2 %<>%
    mp_cal_dist(
      .abundance = hellinger,
      distmethod = "bray"
# PCoA analysis
mpse2 %<>%
    mp_cal_pcoa(
      .abundance = hellinger,
      distmethod = "bray"
pcoaplot1 <- mpse2 %>%
             mp_plot_ord(
               .ord = pcoa,
               .group = Group,
               .starshape = Group,
               .color = Group,
               .size = Observe,
               ellipse = TRUE,
               show.legend = FALSE
            ) +
            scale color manual(
               values = cols
            scale_fill_manual(values = cols) +
            scale_size_continuous(
               range = c(1, 3),
               guide = guide_legend(override.aes = list(starshape = 15))
            ) +
            theme(
               legend.key.width = unit(0.3, "cm"),
               legend.key.height = unit(0.3, "cm"),
               legend.text = element_text(size=6),
               legend.title = element_text(size=7)
# first and third principal co-ordinates
pcoaplot2 <- mpse2 %>%
             mp_plot_ord(
               .ord = pcoa,
               .group = Group,
               .starshape = Group,
               .color = Group,
               .size = Observe,
               ellipse = TRUE,
               .dim = c(1, 3),
               show.legend = FALSE
             ) +
             scale_color_manual(
               values = cols
             scale_fill_manual(
               values = cols
             ) +
             scale_size_continuous(
               range = c(1, 3),
```

```
guide = guide_legend(override.aes = list(starshape = 15))
) +
theme(
    legend.key.width = unit(0.3, "cm"),
    legend.key.height = unit(0.3, "cm"),
    legend.text = element_text(size = 6),
    legend.title = element_text(size = 7)
)
(pcoaplot1 | pcoaplot2) + plot_annotation(tag_levels = "A")
```

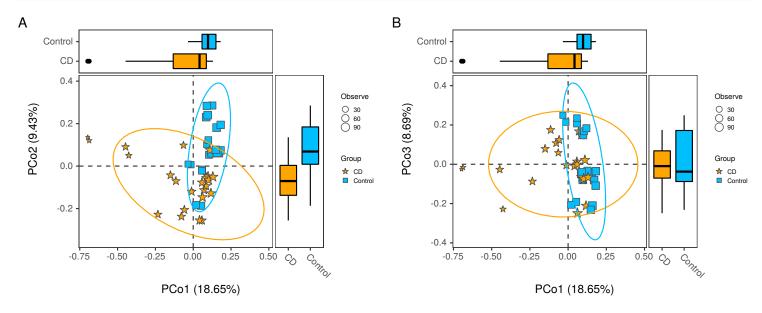

Fig. S8: The PCoA plot based on Bray-Curtis distance.

The result of distance between the samples also can be visualized by mp_plot_dist with heatmap or boxplot.

```
pdist1 <- mpse2 %>%
          mp_plot_dist(
            .distmethod = bray,
            .group = Group
          ) %>%
          set_scale_theme(
            x = scale_fill_manual(
                  values=cols,
                  guide = guide_legend(
                              keywidth = 0.5,
                              keyheight = 0.5,
                              label.theme=element_text(size=6)
                    )
                ),
            aes_var = Group
          ) %>%
          set_scale_theme(
            x = list(scale_size_continuous(range = c(1, 3)),
                     scale_color_viridis_c(option = "H"),
                     theme(
                       legend.key.width = unit(0.3, "cm"),
                       legend.text = element_text(size = 6),
                        legend.title = element_text(size = 7)
                ),
            aes_var = bray
          )
```

Fig. S9: The distance heatmap and the boxplot for each sample. The size and color of the heatmap represent the distance of each sample, the color of bar represent the group of sample (A). The boxplot represent the distance pairs of sample among the group, it show the dissimilarity of sample between the *control* and *CD* is significant, which is consistent with the result of Permutational Multivariate Analysis of Variance 2.5.3.

2.5.3 Permutational Multivariate Analysis of Variance

We also can perform the Permutational Multivariate Analysis of Variance using mp_adonis wrapping the adonis of vegan (Oksanen et al. 2020).

```
mpse2 %<>% mp_adonis(
            .abundance = hellinger,
            distmethod = "bray",
            .formula = ~Group,
            permutation = 9999,
            action = "add")
mpse2 %>%
    mp_extract_internal_attr(name=adonis) %>%
    mp_fortify()
## # A tibble: 3 x 7
##
                  Df SumsOfSqs MeanSqs F.Model
                                                     R2 `Pr(>F)`
     factors
                                          <dbl> <dbl>
##
     <chr>
               <dbl>
                          <dbl>
                                  <dbl>
                                                           <dbl>
                          0.789
                                  0.789
                                           3.88 0.0864
                                                          0.0001
## 1 Group
                   1
```

From the result, we found the *pvalue* of the analysis of *adonis* is smaller than 0.05 for the Group, meaning the dissimilarity of samples between the Group is significant, which is consistent with the 2.5.2.

2.6 biomarker discovery

This package provides mp_diff_analysis to detect the biomarker. And the result (with action = "get") can be visualized by ggdiffbox, ggdiffclade, ggeffectsize, ggdifftaxbar and mp_plot_diff_res (with action = "add"), or displayed manually using ggtree (Yu et al. 2017) and ggtreeExtra (Xu et al. 2021).

```
# for the kruskal_test and wilcox_test
library(coin)
library(MicrobiotaProcess)
# get result (diffAnalysisClass) of the different analysis with action = 'get'.
deres <- mpse2 %>%
         mp_diff_analysis(
            .abundance = RareAundance,
            .group = Group,
            first.test.method = "kruskal_test",
            filter.p = "pvalue",
            first.test.alpha = 0.05,
            strict = TRUE,
            second.test.method = "wilcox_test",
            second.test.alpha = 0.05,
            subcl.min = 3,
            subcl.test = TRUE,
            ml.method = "lda",
            ldascore = 3,
            action = "get"
```

```
# The result of different analysis was added to the taxatree with action = 'add'
mpse2 <- mpse2 %>%
         mp_diff_analysis(
            .abundance = RareAundance,
            .group = Group,
            first.test.method = "kruskal_test",
            filter.p = "pvalue",
            first.test.alpha = 0.05,
            strict = TRUE,
            second.test.method = "wilcox test",
            second.test.alpha = 0.05,
            subcl.min = 3,
            subcl.test = TRUE,
            ml.method = "lda",
            ldascore = 3,
            action = "add"
```

2.6.1 visualization of different results by ggdiffclade

The color of discriminative taxa represent the taxa is more abundant in the corresponding group. The point size shows the negative logarithms (base 10) of pvalue. The bigger size of point shows more significant (lower pvalue), the *pvalue* was calculated in the first step test (default is *kruskal.test*).

```
diffclade_p <- ggdiffclade(</pre>
                   obj=deres,
                   alpha=0.3,
                   linewd=0.15,
                   skpointsize=0.6,
                   layout="radial",
                   taxlevel=3,
                   removeUnkown = TRUE,
                   reduce = FALSE # This argument is to remove the branch of unknown taxonomy.
               scale_fill_manual(
                   values = cols
               ) +
               guides(color = guide_legend(
                                   keywidth = 0.1,
                                   keyheight = 0.2,
                                   order = 3,
                                   ncol=1)
               ) +
               theme(
                   panel.background = element_rect(fill=NA),
                   legend.position = "right",
                   plot.margin = margin(0,0,0,0),
                   legend.key.width = unit(0.2, "cm"),
                   legend.key.height = unit(0.2, "cm"),
                   legend.spacing.y = unit(0.02, "cm"),
                   legend.title = element_text(size=7),
                   legend.text = element_text(size=6),
                   legend.box.spacing = unit(0.02, "cm")
diffclade_p
```

Fig. S11: The taxa tree clade plot of different analysis result (with action = 'get').

We also can visualized the result (default, with action = 'add') via ggtree (Yu et al. 2017) and ggtreeExtra (Xu et al. 2021).

```

Fig. S12: The taxa tree of the community with the relative abundance of each OTU/ASV on sample and the LDA of different OTU/ASV. The taxa tree was built with the taxa of all samples. The high light color of taxa tree represents the phyla of the clade. The external point layer represents the relative abundance of each OTU on sample. The external bar layer represents the LDA of the different OTU. The colored points represent the different taxa, the size of colored point represents the *pvalue* or *fdr*.

To decreases coding burden, we also developed mp_plot_diff_res to visualize the result of different analysis.

```
library(ggplot2)

pp <- mpse2 %>%
    mp_plot_diff_res() +
    scale_fill_manual(
        values = cols
    ) +
    scale_fill_manual(
        aesthetics = "fill_new",
        values = cols
    )

pp
```

Fig. S13: seel also Fig. S12

2.6.2 visualization of differential results (with action = "get") by ggdiffbox

The left panel represents the relative abundance or abundance (according the standard_method) of biomarker, the right panel represents the confident interval of effect size (LDA or MDA) of biomarker. The bigger confident interval shows that the biomarker is more fluctuant, owing to the influence of samples number.

Fig. S14: The boxplot and the LDA score of different taxa. The left panel represents the relative abundance of the different taxa, the right panel represents the LDA effect size (95% confidence interval) of different taxa.

2.6.3 visualization of differential results (with action = "get") by ggdifftaxbar

ggdifftaxbar can visualize the abundance of biomarker in each samples of groups, the mean and median abundance of groups or subgroups are also showed. output parameter is the directory of output.

2.7 Interoperable with the existing computing ecosystem

Because the MPSE object MicrobiotaProcess inherits the SummarizedExperiment object (Morgan et al. 2021), The related inherited methods for signature SummarizedExperiment can also be applied to the MPSE. For example, the tidybulk (Mangiola et al. 2021) provides an R tidy framework for modular transcriptomic data analysis. It provides a test_differential_abundance to perform differential transcription testing using edgeR quasi-likelihood edgeR likelihood-ratio (LR), limma-voom, limma-voom-with-quality-weights or DESeq2. It is also compatible with MPSE.

```
library(tidybulk)
library(edgeR)
library(aplot)
library(shadowtext)
library(ggrepel)
mpse2 %<>% test_differential_abundance(.abundance = Abundance, .formula = ~Group)
# extract the different OTUs from the MPSE class
res <- mpse2 %>% dplyr::filter(FDR <= .05 & abs(logFC) >= 2)
pp <- res %>%
      mp_plot_abundance(
        .abundance = RareAbundance,
        force = TRUE,
       relative = TRUE,

We compared the different result between the edgeR (Robinson, McCarthy, and Smyth 2010) and MicrobiotaProcess. We found the number of the different OTUs based on edgeR is more than the MicrobiotaProcess. We think this is because we didn't remove the low-abundance OTUs in the analysis using tidybulk. This operation is generally needed in standard whole-transcriptome workflows. However, if it is preformed in the microbiome analysis, many low-abundance OTUs will be removed. More different OTUs were identified by the operation using edgeR (Robinson, McCarthy, and Smyth 2010).

Then we extract the same different OTUs, we found the abundance of same OTUs belonged to *Bifidobacterium*, *Faecalibacterium*, *Roseburia* and *Coprobacillus* were significantly decreased in CD group compared to the Control group, the abundance of several OTUs belonged to *Escherichia*, *Klebsiella* and *Haemophilus*, which belonged to Gammaproteobacteria, were significantly enriched in CD group.

Fig. S15: The results of different OTUs based on the edgeR_quasi_likelihood with tidybulk (A). The relative abundance heatmap of the different OTUs. (B). The hierarchical cluster of samples based on the relative abundance of the different OTUs. (C). The hierarchical cluster of OTUs based on the relative abundance of total OTUs, the different OTUs were labeled with their names. We found the cluster of different OTUs in the heatmap is consistent with the different OTUs in the background of total OTUs (C).

3 the analysis of the other published pediatric CD stool samples

In the previous chapter, we described how to use *MicrobiotaProcess* to do the analysis of the 16s rDNA data. However, it also can be applied to metagenome or metatranscriptome species community data and the function data analysis. In this chapter, we used the example datasets about the other published pediatric CD stool microbial study (Douglas et al. 2018) to show how to used *MicrobiotaProcess* to do the related analysis. The datasets were obtained from the github². To avoid duplication, we only show how to import the 16s dataset, we focused on the analysis of metagenomics and KEGG gene datasets.

3.1 Loading the 16s data and construction of MPSE class

The chapter is similar with the 3, so some operations can refer to the previous chapter 3.

```

²https://github.com/LangilleLab/CD RF microbiome

3.2 Loading the KEGG data

The KEGG gene abundances were annotated based on the MGS data. It can also be imported as MPSE, and further analyzed using *MicrobiotaProcess*. Here, we only show how to identify the different gene using the $mp_diff_analysis$ of *MicrobiotaProcess* (refer to chapter 3.3). Other operations are similar with the analysis of 16s rDNA data (refer to chapter 3).

```
KO.da <- read.table("./data/CD_RF_microbiome/biscuit_mgs_KOs.tsv", header=TRUE, sep = "\t", row.names=1, check.
# Building the MPSE object.
mpseKO <- MPSE(assays=list(Abundance = KO.da))
# merge the sample metadata information.
mpseKO %<>% left_join(sample.da, by=c("Sample"="sample_id"))
```

3.2.1 Different analysis for KEGG genes abundance

The metrics of the KEGG genes is the relative abundance, here we used $mp_diff_analysis$ to identify the difference KEGG genes with 'force = TRUE and relative = FALSE', meaning the relative abundance will be used directly.

```
mpseKO %<>%
    mp_diff_analysis(
        .abundance = Abundance,
    force = TRUE,
    relative = FALSE,
        .group = disease,
    filter.p = "pvalue"
)
```

Then we can perform the KEGG pathway enrichment analysis using clusterProfiler (Wu et al. 2021) and MicrobiomeProfiler (Chen and Yu 2021) developed by us.

```
# perform KEGG pathway analysis with clusterProfiler and MicrobiomeProfiler
com.xx <- mpseKO %>%
    mp_extract_feature() %>% # Extracting the feature metadata information
    dplyr::filter(pvalue <= 0.05) %>% # Extracting the features pvalue <= 0.05
    compareCluster(OTU~Sign_disease, data=., fun=enrichKO)
# visualizing the enriched pathway with dotplot
p.dot <- dotplot(com.xx) +</pre>
         scale_color_gradientn(
           colours = c("#b3eebe", "#46bac2", "#371ea3"),
           guide = guide_colorbar(reverse=TRUE, order=1)
         ) +
         labs(x = NULL) +
         guides(size = guide_legend(override.aes=list(shape=1))) +
           panel.grid.major.y = element_line(linetype='dotted', color='#808080'),
           panel.grid.major.x = element_blank()
# with network plot
set.seed(1024)
p.net <- cnetplot(</pre>
           com.xx,
           layout = "fr",
           cex_label_category = 1.8
         scale_fill_manual(
           values = cols
p <- aplot::plot_list(p.net, p.dot, widths = c(3, 1), tag_levels="A")</pre>
```

A B

Fig. S17: The result of KEGG pathway enrichment analysis

3.3 Loading the MGS data

The taxa abundance data also can be analyzed by MicrobiotaProcess, Here we used the example data from output of MetaPhlAn (Segata et al. 2012) to show how to perform the related analysis using MicrobiotaProcess. The output of other taxa abundance can also be imported and converted to the MPSE object, and be further analyzed using MicrobiotaProcess, which can refer to chapter 3.2 and chapter 4.

```
# This is the output of MetaPhlAn2, which might need to specific the 'linenum'
# base on the first several rows whether to contain the metadata information
mpseMGS <- mp import metaphlan("./data/CD RF microbiome/metaphlan2 out merged species.tsv", linenum=1)
# rename the column names of MPSE.
colnames(mpseMGS) <- mpseMGS %>% mp_extract_sample %>% pull(2)
mpseMGS %<>% left_join(sample.da, by=c("Sample"="sample_id"))

```

3.3.1 Alpha diversity analysis in MGS level

The metric of Metagenomics data usually is relative abundance. But the some functions of MicrobiotaProcess need to require the abundance is count (in default). To process the relative abundance (not integer), We can specific 'force = TRUE', which meaning the corresponding functions will be calculated directly without rarefied.

```
mpseMGS %<>%
    mp_cal_alpha(
        .abundance = Abundance,
        force = TRUE
    )

p <- mpseMGS %>%
        mp_plot_alpha(
        .group = disease,
        .alpha = c(Observe, Shannon, Pielou)
    ) +
    scale_color_manual(values = cols) +
    scale_fill_manual(values = cols) +
    theme(legend.position = "none")

p
```

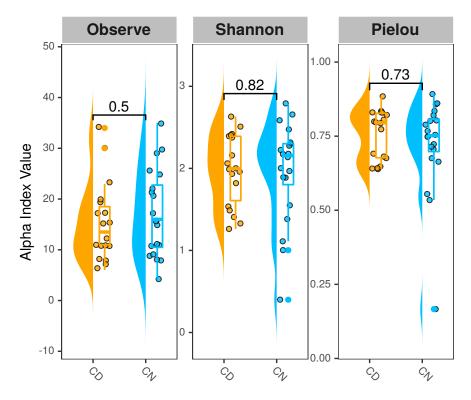

Fig. S18: The alpha diversity boxplot based on MGS data

3.3.2 Beta diversity analysis in MGS level

We used mp_cal_dist to calculated the distance between the samples, then used mp_plot_dist to display the distance with heatmap (Fig.S19.A) and boxplot (Fig.S19.B), then the distance was used to perform the PCoA analysis (Fig.S19.C).

```
mpseMGS %<>%
   mp_decostand(
      .abundance = Abundance,
      method = "hellinger"
    )
mpseMGS %<>%
    mp_cal_dist(
      .abundance = hellinger,
      distmethod = "bray"
    )
mpseMGS %<>%
    mp_cal_pcoa(
      .abundance = hellinger,
      distmethod = "bray"
    )
p1 <- mpseMGS %>%
      mp_plot_dist(
        .distmethod = bray,
        .group=c(disease, response)
      ) %>%
      set_scale_theme(
        x = scale_fill_manual(
              values = cols,
              guide = guide_legend(
                           keywidth = 0.5,
                           keyheight = 0.5,
                           label.theme=element_text(size=6)
                 )
            ),
        aes_var = disease
      ) %>%
      set_scale_theme(
        x = scale_fill_manual(
              values=cols2,
              guide = guide_legend(
                           keywidth = 0.5,
                           keyheight = 0.5,
                           label.theme=element_text(size=6)
                 )
            ),
        aes_var = response
      ) %>%
      set_scale_theme(
        x = scale_size_continuous(
              range = c(1, 3),
              guide = guide_legend(
                           keywidth = 0.5,
                           keyheight = 0.5,
                           label.theme=element_text(size=6)
                 )
            ),
        aes_var = bray
```

```
p2 <- mpseMGS %>%
      mp_plot_dist(
        .distmethod = bray,
        .group = disease,
       group.test = TRUE
      ) +
      scale_color_manual(
        values = c("orange", "#00A08A", "deepskyblue")
      scale_fill_manual(
        values = c("orange", "#00A08A", "deepskyblue")
p3 <- mpseMGS %>%
      mp_plot_ord(
       .ord = pcoa,
       .group = disease,
        .size = Observe,
        .starshape = response,
        show.side = FALSE
      ) +
      scale_starshape_manual(values = c(1, 13, 15)) +
      scale fill manual(
       values=cols,
        guide=guide_legend(
          keywidth = 0.3,
          keyheight = 0.3,
          label.element = element_text(size = 6),
          override.aes = list(size = 2, starshape = 15)
        )
      ) +
      scale_size_continuous(
       range = c(1, 3),
        guide = guide_legend(
          keywidth = 0.3,
          keyheight = 0.3,
          label.element = element_text(size = 6),
          override.aes = list(starshape = 15)
        )
      )
design <- "\n111\n111\n111\n233\n233\n"
aplot::plot_list(p1, p2, p3, design = design, tag_levels = "A")
```

Then we used mp_adonis to perform the Permutational Multivariate Analysis of Variance based on the distance.

```
mpseMGS %<>%
    mp_adonis(
        .abundance = Abundance,
        .formula = ~ disease + response,
        distmethod = "bray",
        permutation = 9999,
        action = "add"
    )
# the result can be extracted with mp_extract_internal_attr
# mpseMGS %>% mp_extract_internal_attr(name = adonis)
```

3.3.3 Different analysis in MGS level

Here, we also used $mp_diff_analysis$ to detect the difference taxa, we also specified the 'force = TRUE' and 'relative = FALSE', meaning the metric of abundance (abundance) was used to perform the analysis directly without rarefied and calculated the relative abundance (Fig.S20).

```
mpseMGS %<>%
    mp_diff_analysis(
       .abundance = Abundance,
       force = TRUE,
       relative = FALSE,
       .group = disease,
       filter.p = "pvalue"
    )
library(forcats)
trda <- mpseMGS %>% mp_extract_tree()
p <- ggtree(trda, layout = 'radial') +</pre>
     geom_tiplab(size = 1.8, offset = 11) +
     geom_hilight(
         mapping = aes(
           subset = nodeClass == "Phylum",
           node = node,
           fill = label
     )
p2 <- p +
      ggnewscale::new_scale_fill() +
      geom_fruit(
         data = td_unnest(AbundanceBySample, names_repair=tidyr::tidyr_legacy),
         geom = geom_star,
         mapping = aes(
            x = fct_reorder(Sample, disease, .fun=min),
            size = Abundance,
            fill = disease,
            subset = Abundance > 0
         ),
         starshape = 13,
         offset = 0.02,
         pwidth = 1,
         grid.params = list(linetype=2)
      ) +
      scale size continuous(name="Relative Abundance (%)",range = c(1, 3)) +
      scale_fill_manual(values = cols)
p3 <- p2 +
      ggnewscale::new_scale("fill") +
      geom_fruit(
         geom = geom_col,
         mapping = aes(
                       x = LDAmean,
                       fill = Sign_disease,
                       subset = !is.na(LDAmean)
                       ),
         orientation = "y",
         offset = .05,
         pwidth = 0.5,
         width = 0.5, # the parameter of geom_col
         axis.params = list(axis = "x",
                             title = "Log10(LDA)",
```

```
title.height = 0.001,
                            title.size = 2,
                            text.size = 1.8,
                            vjust = 1),
         grid.params = list(linetype = 1)
      ) +
      ggnewscale::new_scale("size") +
      geom_point(
         data=td_filter(!is.na(pvalue)),
         mapping = aes(size = -log10(pvalue),
                       fill = Sign_disease
                   ),
         shape = 21
      ) +
      scale_size_continuous(range=c(0.5, 3)) +
      scale_fill_manual(values=cols) +
      theme(
           legend.key.height = unit(0.3, "cm"),
           legend.key.width = unit(0.3, "cm"),
           legend.spacing.y = unit(0.02, "cm"),
           legend.text = element_text(size = 7),
           legend.title = element_text(size = 9),
      )
рЗ
```

Next, we extract the abundance of the different species, then using ggplot2 (Wickham 2011) to visualize them (Fig.S21).

```
deT <- mpseMGS %>% mp_extract_tree() %>% dplyr::filter(!is.na(fdr) & isTip, keep.td=F) %>% dplyr::pull(label)
mpseMGS %>%
    mp_extract_abundance(taxa.class="OTU") %>%
    dplyr::filter(label %in% deT) %>%
    tidyr::unnest(AbundanceBySample) %>%
    ggplot(mapping=aes(x=disease, y=Abundance, fill=disease)) +
    geom_boxplot() +
    facet_wrap(facets = vars(label), nrow = 1, scales = "free", strip.position = "right") +
    ggsignif::geom_signif(comparisons=list(c("CD", "CN"))) +
    scale_fill_manual(values=cols, guide="none") +
    labs(x=NULL, y="relative abundance (%)")
```

The analysis of the mosquito ecology data using MicrobiotaProcess

MicrobiotaProcess also can be used to perform the other related ecology data analysis, besides the microbial community data. Here, we used an example data about a Mosquito ecology study (REISKIND et al. 2017) to show how to use MicrobiotaProcess to perform the analysis of the related ecology study. The data was obtained from the github³.

Loading data and Construction of MPSE object

The 1 to 14 columns are the sample metadata including the study site, and habitat, etc. and the others columns represent the abundance of mosquito species the in each sample.

```
data <- read.csv("./data/Mosquito_ecology/data.csv", row.names=1)</pre>
abun.d <- data[, 14:36]
sample.d <- data[, 1:13]</pre>
# We implements `MPSE` function to build the `MPSE` object, which requires the abundance table (matrix-like).
mpse <- MPSE(assays=list(Abundance=t(abun.d)), colData=sample.d)</pre>
mpse
## # A MPSE-tibble (MPSE object) abstraction: 1,035 x 16

```

Then We can use $mp_diff_analysis$ to identify the species that have significant differential abundance between the **field** and **forest**. We found the Cx.sal ($Culex\ salinarius$) and Ps.col ($Psorophora\ columbiae$) were significantly enriched in **field**, However, the Ae.albo ($Aedes\ albopicta$), Ae.cin ($Aedes\ cinereus$), Ps.fer ($Psorophora\ ferox$), Ae.tris ($Aedes\ triseriatus$), Ae.can ($Aedes\ canadensis$), Ae.hen ($Aedes\ hendersoni$), Ae.atl ($Aedes\ atlanticus$) and Ae.dup ($Aedes\ dupreei$) were significantly enriched in the **forest**

```
dplyr::filter(Habitat %in% c("Field", "Forest")) %>%
    dplyr::mutate(Habitat = as.vector(Habitat)) %>%
    mp diff analysis(.abundance=Abundance, force=T, relative=T, .group=Habitat) %>%
    mp_extract_feature() %>%
    dplyr::filter(fdr<=0.05) %>%
    print(width=200)

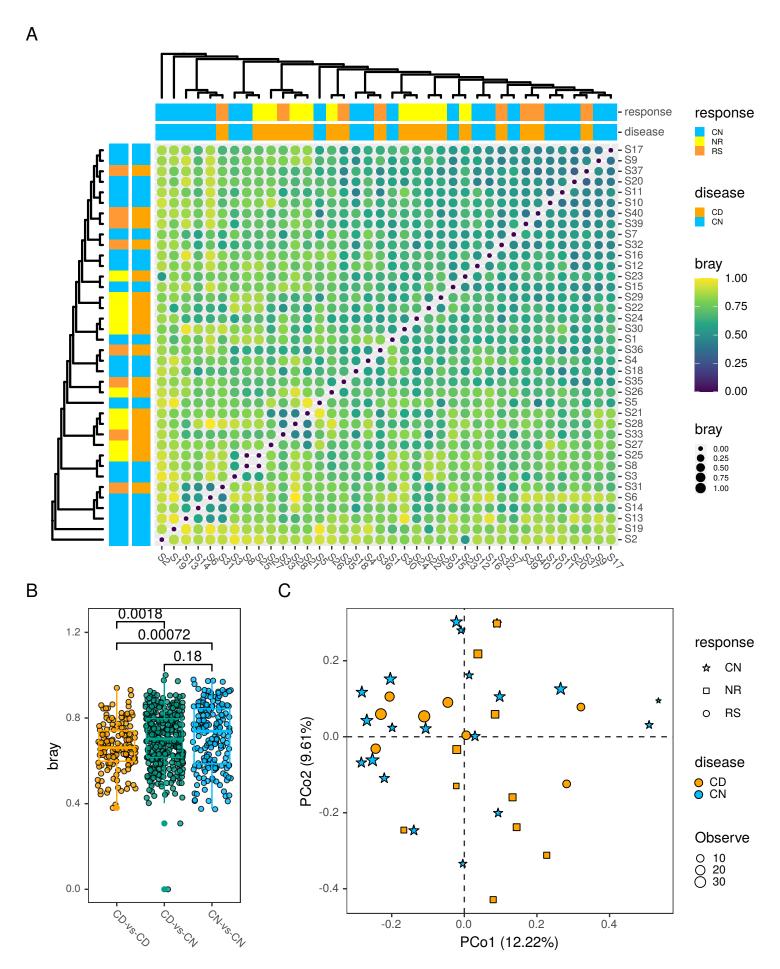

Fig. S19: The distance heatmap and boxplot and the PCoA plot based on the MGS data

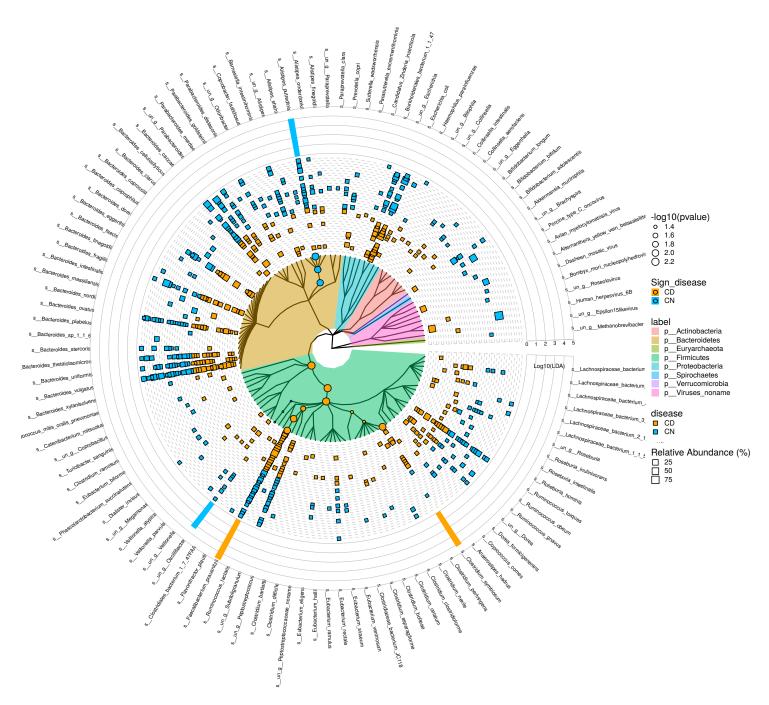

Fig. S20: The result of differential analysis based on the MGS data

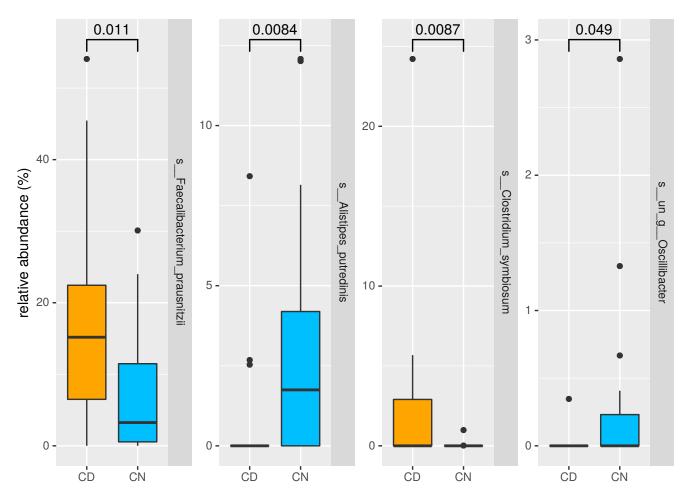

Fig. S21: The abundance boxplot of the differential species between the CD and control group

Fig. S22: The raincloud plot of the alpha diversity of the Mosquito ecology community. The result of the alpha diversity analysis about the Mosquito ecology study showed that the Mosquito species richness gradually increases from field to forest (field --> near field --> edge --> near field --> forest).

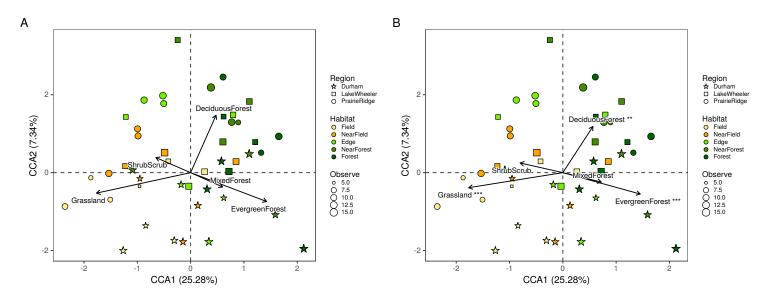

Fig. S23: The CCA plot of the Mosquito ecology study (A) without the result of mp_envfit (B) with the result of mp_envfit . Each point represents one sample, the size of the points represents the observe species of the corresponding sample, the color of the points represents the habitat of the corresponding sample, the shape of points represents the Region of the corresponding sample. And the arrows represent the environment factors, the marked ones by star represent significant related to the Mosquito communities in the study (* 0.05, ** 0.01, *** 0.001).

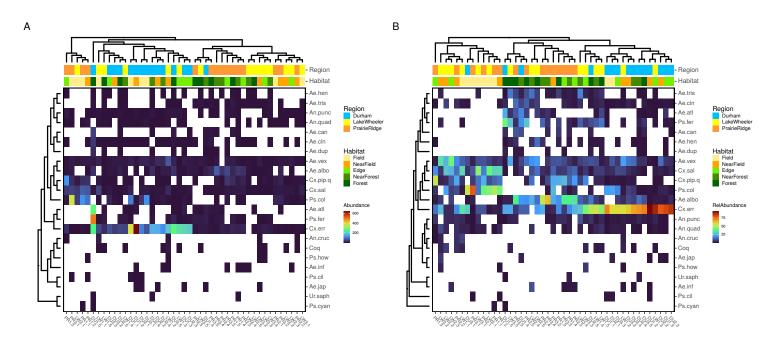

Fig. S24: The heatmap of the abundance (A) and relative abundance (B) of the Mosquito species.
